Exercise training and testing in patients with heart failure Charlotta Lans, 2020-12-15 Patients with heart failure HF suffer from symptoms such as dyspnea fatigue and reduced quality of life which affect their physical function and often lead to immobilization and poor survival prognosis Exercise training in cardiac rehabilitation should be offered to every patient with HF and can be performed both in a hospital setting and with a home training programme Exercise in patients with HF improves physical function and functional capacity as well as health related quality of life HRQoL and reduces the need for hospital care There are several barriers against participating in exercise based cardiac rehabilitation despite information about its benefits The patient may anticipate not being able to exercise that the exercise would be too hard lives far away or has not been referred Aim The aim of this thesis was to evaluate the effects of exercise in heart failure patients of a one year training programme with hospital based training followed by a home based setting or only home based with special emphasis on peripheral muscle training PMT Furthermore to study frequently used methods for evaluation of the effects i.e. the 6 minute walk test and instruments for estimating health related quality of life Methods and findings In study I PMT was evaluated and the PMT

programme in a hospital setting with equipment and subsequent homebased training with elastic bands was compared with solely home based training over 1 year At follow up every third month duplicated six minute walk test 6MWT and two HRQoL questionnaires were used The walking distance increased significantly after three months in both groups and was maintained thereafter Also HRQoL increased but at different time points In study II PMT was compared with interval training on an ergometer bike free walking Both groups started under supervision of a physiotherapist in a hospital setting for three months and thereafter at home for nine months The same measurements were used as in study I Neither walking distance nor HRQoL changed over the study period However this may be regarded as a positive effect in the light of the known progressive nature of heart failure In study III the 6MWTs from study I and II were used to evaluate the necessity of performing duplicated 6MWTs in follow ups clinically and for research purposes We found that it is sufficient to perform one 6MWT In study IV both 6MWT and HRQoL forms from study I and II were used to investigate the relationship between walking distance and perceived HRQoL in HF patients Patients with shorter walking distance than the group median experienced poorer general HRQoL but not HRQoL related to HF than the higher performing half of the study group There were no longitudinal trends in these relationships Conclusion PMT can be used as an exercise modality in patients with HF both in hospital and at home and may be evaluated with a single 6MWT Shorter walking distance was related to a lower general HRQoL as judged by the patients but there was no significant relation between short walking distance and the HF related HRQoL Individualizing the training programme and methods and offering the choice of exercise modality and the possibility of exercising at home might be a way to increase adherence in cardiac rehabilitation
