Enzymes specifically break a substrate into smaller products in specific chemical subregions. Methylase adds and removes (methylates and demethylates) methyl groups to specific sites on a DNA molecule. (Methylase does not remove the methyl group, but it transfers the methyl group to another molecule.)

However, when in very dry places where the upper surface of the cell wall and smaller components of plasma membrane rupture, the organism survives using an "air-drying" strategy. During this process, what is the relationship? What is the main component?
