Data-Driven Insights for Supply Chain Optimization: Frameworks and Solutions using AI Anil K Anusuru, 2025-02-08

Our supply chain (SC) model is based on a two-tier queueing inventory system. This facility delivers packages of $Q > 0$ fixed-size items from its inventory stored in a distribution centre (DC) to a retail shopping mall (RSM). This RSM processes customer requirements through an $M/M/1/K$ rule service facility. Requests to the RSM node follow the Poisson process with the parameter λ . The inventory guideline applied at node RSM is of type $(Q, 0)$, and the order of most items $Q > 0$ is placed on the DC when inventory decreases from Q to level 0 with a threshold guideline called f policy. Thus, at the end of the delay, the DC output of the quantity ordered by RSM is exponentially distributed with the parameter λ . For each request to the RSM node, an article is only available after the exponential service time with the parameter μ . The waiting room at the commercial node has unlimited capacity. This SC management (SCM) is called a queue inventory system with a f_1 policy. The common stochastic process $\{Z(t), N(t), I(t)\}$ to link the number of customers, demands available at time t by $N(t)$, and the on-hand inventory level by $I(t)$ is formulated. Because of the properties of the exponential distributions and of the f_1 policy, this pair sequence $\{Z(t)\}$ forms a Markov decision process (MDP) that changes its states with the passage of times t . The Z system's stationary properties are checked at service completion. We also use the linear function of total expected cost to determine the optimal order quantity and optimal order patterns. Using the same methodology, the analysis is extended by assuming that the two processes are independent under a new policy f_2 . Numerical

illustrations are also provided to support the results obtained from the proposed MDP approach
